Scheduling: Proportional Share

CMPU 334 – Operating Systems
Jason Waterman
Proportional Share Scheduler

• Fair-share scheduler
  • Guarantee that each job obtain a certain percentage of CPU time
  • Not optimized for turnaround or response time
Basic Concept

• Tickets
  • Represent the share of a resource that a process should receive
  • The percent of tickets represents its share of the system resource in question

• Example
  • There are two processes, A and B
  • Process A has 75 tickets → receive 75% of the CPU
  • Process B has 25 tickets → receive 25% of the CPU
Lottery scheduling

- The scheduler picks a winning ticket
  - Switch to the winning process and run it

Example
- There are 100 tickets
  - Process A has 75 tickets: 0 to 74
  - Process B has 25 tickets: 75 to 99

Scheduler’s winning tickets:  63  85  70  39  76  17  29  41  36  39  10  99  68  83  63

Resulting scheduler: A  B  A  A  B  A  A  A  A  B  A  B  A

A runs 11/15 = 73.3%, B runs 4/15 = 26.7%

The longer these two jobs compete, the more likely they are to achieve the desired percentages
Ticket Mechanisms

• Ticket currency
  • A user allocates tickets among their own jobs in whatever currency they would like
  • The system converts the currency into the correct global value
• Example
  • There are 200 tickets (Global currency)
  • Process A has 100 tickets
  • Process B has 100 tickets

User A  $\rightarrow$ 500 (A’s currency) to A1  $\rightarrow$ 50 (global currency)
         $\rightarrow$ 500 (A’s currency) to A2  $\rightarrow$ 50 (global currency)

User B  $\rightarrow$ 10 (B’s currency) to B1  $\rightarrow$ 100 (global currency)
Ticket Mechanisms (Cont.)

• Ticket transfer
  • A process can temporarily hand off its tickets to another process

• Ticket inflation
  • A process can temporarily raise or lower the number of tickets it owns
  • If any one process needs more CPU time, it can boost its tickets
  • Assumes processes cooperate and are friendly with each other
Implementation

- Example: There are three processes, A, B, and C
- Keep the processes in a list:

```
int counter = 0;
int winner = getrandom(0, totaltickets);
node_t *current = head;
```

```
while (current) {
    counter = counter + current->tickets;
    if (counter > winner)
        break; // found the winner
    current = current->next;
}
```

// 'current' is the winner: schedule it...

```
Job:A
Tix:100
```

```
Job:B
Tix:50
```

```
Job:C
Tix:250
NULL
```
Implementation (Cont.)

• $U$: unfairness metric
  • The time the first job completes divided by the time that the second job completes

• Example:
  • There are two jobs, each job has runtime 10
    • First job finishes at time 10
    • Second job finishes at time 20
  • $U = \frac{10}{20} = 0.5$
  • $U$ will be close to 1 when both jobs finish at nearly the same time
Lottery Fairness Study

• There are two jobs
  • Each jobs has the same number of tickets (100)

When the job length is not very long, average unfairness can be quite severe
Lottery Discussion

• Simplicity of implementation
  • Random number generator
  • List of processes
  • Total number of tickets

• How do you assign tickets?
  • Tough problem
  • System behavior depends on how tickets are allocated

• Let the users decide how to allocate tickets?
Stride Scheduling

- Random is easy to implement, but may not deliver the exact right proportions

- **Stride** of each process
  - (A large number) / (the number of tickets of the process)
  - Example: A large number = 10,000
    - Process A has 100 tickets → stride of A is 100
    - Process B has 50 tickets → stride of B is 200

- A process runs, increment a counter (=pass value) for it by its stride
  - Pick the process to run that has the lowest pass value

```c
current = remove_min(queue); // pick client with minimum pass
schedule(current);            // use resource for quantum
current->pass += current->stride; // compute next pass using stride
insert(queue, current);       // put back into the queue
```

A pseudo code implementation
### Stride Scheduling Example

<table>
<thead>
<tr>
<th>Pass(A) (stride=100)</th>
<th>Pass(B) (stride=200)</th>
<th>Pass(C) (stride=40)</th>
<th>Who Runs?</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>A</td>
</tr>
<tr>
<td>100</td>
<td>0</td>
<td>0</td>
<td>B</td>
</tr>
<tr>
<td>100</td>
<td>200</td>
<td>0</td>
<td>C</td>
</tr>
<tr>
<td>100</td>
<td>200</td>
<td>40</td>
<td>C</td>
</tr>
<tr>
<td>100</td>
<td>200</td>
<td>80</td>
<td>C</td>
</tr>
<tr>
<td>100</td>
<td>200</td>
<td>120</td>
<td>A</td>
</tr>
<tr>
<td>200</td>
<td>200</td>
<td>120</td>
<td>C</td>
</tr>
<tr>
<td>200</td>
<td>200</td>
<td>160</td>
<td>C</td>
</tr>
<tr>
<td>200</td>
<td>200</td>
<td>200</td>
<td>...</td>
</tr>
</tbody>
</table>

If new job enters with pass value 0, it will **monopolize** the CPU!
The Linux Completely Fair Scheduler (CFS)

• Implements fair-share scheduling

• Efficient and scalable
  • Quickly make a scheduling decision

• Scheduling performance is important
  • Scheduling uses about 5% of datacenter CPU time at Google
CFS Basic Operation

• Fairly divides a CPU evenly among all competing (Runnable) processes
  • Doesn’t use a fixed time slice
• Uses the **virtual runtime** (*vruntime*) of a process
  • Accumulates as the process runs
  • To schedule a process, pick the one with the lowest *vruntime*
• When to schedule?
  • Frequent switches increase fairness but has a higher overhead
  • Fewer switches give better performance at the cost of fairness
• Controlled by `sched_latency` parameter
  • Maximum time a process can run before considering a switch (e.g., 20 ms)
  • Divided by the number of runnable processes to get a process time slice
  • CFS will be completely fair over this time period
CFS Example

- `sched_latency` = 48 ms

- Four processes that are runnable to start
  - Per process time slice of 12 ms (48/4)
  - `vruntime` is starts at 0 for these jobs

- Pick job with the lowest `vruntime` (A, B, C, or D in this case)

- Run job A until it has used 12 ms of `vruntime`
  - Then make a scheduling decision
  - Run the job with the lowest `vruntime`
    - (B, C, or D)

- C and D complete after 96 ms
  - Time slice is adjusted to 24 ms (48/2)
Too many processes runnable?

- **Per process time slice is the `sched_latency` / runnable processes**
  - A lot of runnable processes could lead to small time slices
    - Lots of context switches and more overhead

- **CFS `min_granularity` parameter**
  - Minimum time slice of a process (e.g., 6 ms)
  - CFS will never set the time slice of a process to less than this value
  - In this case, may not be perfectly fair over the target scheduling latency
    - E.g., `sched_latency` = 48 ms with 10 runnable processes
      - time slice 4.8 --> 6 ms
      - all jobs won’t run during the 48 ms

- **Timer interrupts**
  - Time slices are variable, how to set the timer?
  - Timer goes off frequently (e.g., 1 ms)
  - Gives the CFS scheduler a chance to see if the current job has reached the end of its run
Niceness Levels

• Gives the user control over process priority
  • Give some processes a higher (or lower) share of the CPU

• Not through tickets, but with a **nice** level of a process
  • A measure of how nice (to other processes) your job is
  • 19 (lowest priority)
  • -20 (highest priority)

• Nice levels are mapped to a weight used to compute an effective time slice for a process
Niceness Weightings

```c
static const int prio_to_weight[40] = {
    /* -20 */  88761,  71755,  56483,  46273,  36291,
    /* -15 */  29154,  23254,  18705,  14949,  11916,
    /* -10 */  9548,   7620,   6100,   4904,   3906,
    /* -5 */   3121,   2501,   1991,   1586,   1277,
    /*  0 */   1024,   820,    655,    526,    423,
    /*  5 */   335,    272,    215,    172,    137,
    /* 10 */   110,    87,     70,     56,     45,
    /* 15 */   36,     29,     23,     18,     15,
};
```

time_slice_k = \( \frac{\text{weight}_k}{\sum_{n=0}^{n-1} \text{weight}_i} \) \cdot \text{sched\_latency}
Niceness Weighting Example

• Two processes, A and B
  • A’s niceness level is -5 (boost in priority)
  • B’s niceness level is 0 (default)

• Calculate the time slice for A and B
  • Weight A: 3121, weight B: 1024, total weight: 4145
  • Time slice A: 3121 / 4145 = 0.753 * sched_latency
  • Time slice B: 1024 / 4145 = 0.247 * sched_latency

• Assuming a 48 ms sched_latency:
  • Process A gets about 75% of the sched_latency (36 ms)
  • B gets about 25% of the sched_latency (12 ms)

• Weight table is constructed to preserve CPU proportionally ratios when the difference in nice values is constant
  • E.g., if process A had a nice value of 5 and B had a nice value of 10, they would be scheduled the same way as above
Calculating vruntime

• Higher priority processes get a longer time slice
• But we pick the process with the lowest vruntime to run next
  • To handle priority properly, vruntime must scale inversely with priority
• For our example:
  • A’s vruntime will accumulate at about a 1/3 the rate of B’s

\[ vruntime_i = vruntime_{i-1} + \frac{weight_0}{weight_i} \cdot runtime_i \]
CFS efficiency

- How quickly can the scheduler find the next job to run
  - Lists don’t scale if you have 1000s of processes to search through ever millisecond

- CFS keeps processes in a red-black tree
  - A type of balanced tree
  - Does a little extra work to maintain low depths
  - $O(\log n)$ for operations (search, insert, delete)

- CFS only keeps running and runnable processes in this structure
  - If a process is waiting on I/O, it is removed from the tree and kept track elsewhere
  - What to do when process wakes up?
    - vruntime will be behind the others and could monopolize the CPU
    - CFS sets the vruntime for the job to the minimum value found in the tree
    - Jobs that sleep for short periods often do not ever get their fair share of the CPU
Summary

• We looked at three proportional share schedulers

• Lottery scheduling
  • Uses randomness to achieve proportional share
  • Can be unfair with short running jobs
  • Can be implemented with no shared state between processes
  • Ticket allocation can be difficult

• Stride scheduling
  • Achieves proportional share deterministically

• Linux Completely Fair Scheduler (CFS)
  • Most widely used fair-share scheduler in existence
  • A bit like a weighted round-robin with dynamic time slices
  • Built to scale and perform well under load
